

Pharmacology I

Cell Wall Inhibitors

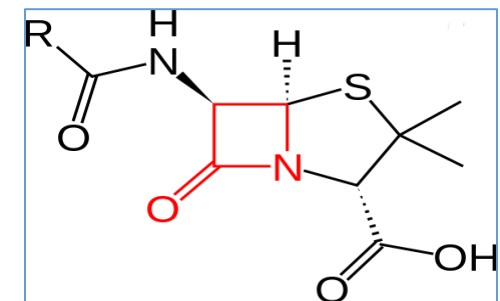

Dr. Marwan Al-Zubeidy

Lecture No. : 8

مستقبل له تاريخ

Cell Wall Inhibitors

- **Penicillins and cephalosporins** are the major antibiotics that inhibit bacterial cell wall synthesis.
- They are called beta-lactams because of the **4-member ring** that is common to all their members.
- The beta-lactams include some of the most effective, widely used, and well-tolerated agents available for the treatment of microbial infections.

Cell Wall Inhibitors

1

Penicillins

2

7

Others

- Synthetic Production of Penicillin
Professor Alexander Fleming, holder of the Chair of Bacteriology at London University, **who first discovered the mould Penicillium notatum**.
- Here in his laboratory at St Mary's, Paddington, London.

PENICILLINS	
<i>Amoxicillin</i> *	AMOXIL
<i>Ampicillin</i> **	GENERIC ONLY
<i>Dicloxacillin</i> *	GENERIC ONLY
<i>Nafcillin</i>	GENERIC ONLY
<i>Oxacillin</i>	GENERIC ONLY
<i>Penicillin G</i>	PFIZERPEN
<i>Penicillin G benzathine</i>	
<i>Penicillin G benzathine G procaine</i>	BICILLIN C-R
<i>Penicillin V</i> *	GENERIC ONLY

CARBAPENEMS	
<i>Doripenem</i>	DORIBAX
<i>Ertapenem</i>	INVANZ
<i>Imipenem/cilastatin</i>	
<i>Meropenem</i>	MERREM

MONOBACTAMS	
<i>Aztreonam</i>	AZACTAM

CEPHALOSPORINS	
<i>Cefaclor</i> *	GENERIC ONLY
<i>Cefadroxil</i> *	GENERIC ONLY
<i>Cefazolin</i>	ANCEF, KEFZOL
<i>Cefdinir</i> *	OMNICEF
<i>Cefepime</i>	MAXIPIME
<i>Cefixime</i> *	SUPRAX
<i>Cefotetan</i>	CEFOTAN
<i>Cefoxitin</i>	MEFOXIN
<i>Cefprozil</i> *	CEFZIL
<i>Ceftaroline</i>	TEFLARO
<i>Ceftazidime</i>	FORTAZ
<i>Ceftriaxone</i>	GENERIC ONLY
<i>Cefuroxime</i> **	CEFTIN, ZIN
<i>Cephalexin</i> *	KEFLEX

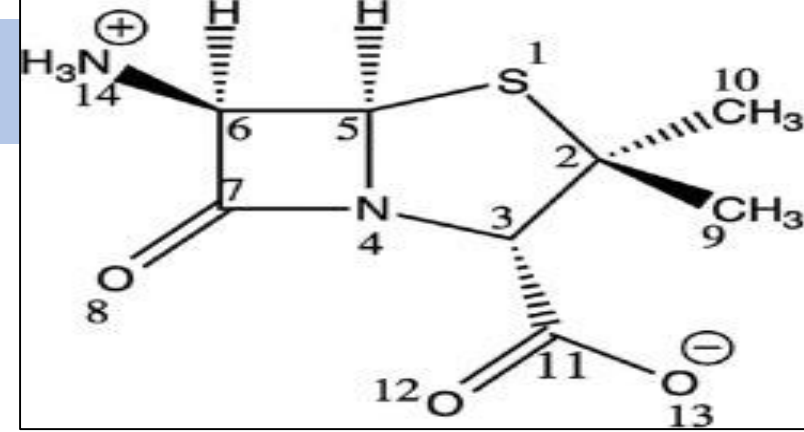

β -LACTAMASE INHIBITOR + ANTIBIOTIC COMBINATIONS	
<i>Avibactam + ceftazidime</i>	AVYCAZ
<i>Clavulanic acid + amoxicillin</i>	
	AUGMENTIN
<i>Sulbactam + ampicillin</i>	UNASYN
<i>Tazobactam + ceftolozane</i>	ZERBAXA
<i>Tazobactam + piperacillin</i>	ZOSYN
<i>Vaborbactam + meropenem</i>	VABOMERE

LIPOGLYCOPEPTIDES	
<i>Dalbavancin</i>	DALVANCE
<i>Oritavancin</i>	ORBACTIV
<i>Telavancin</i>	VIBATIV

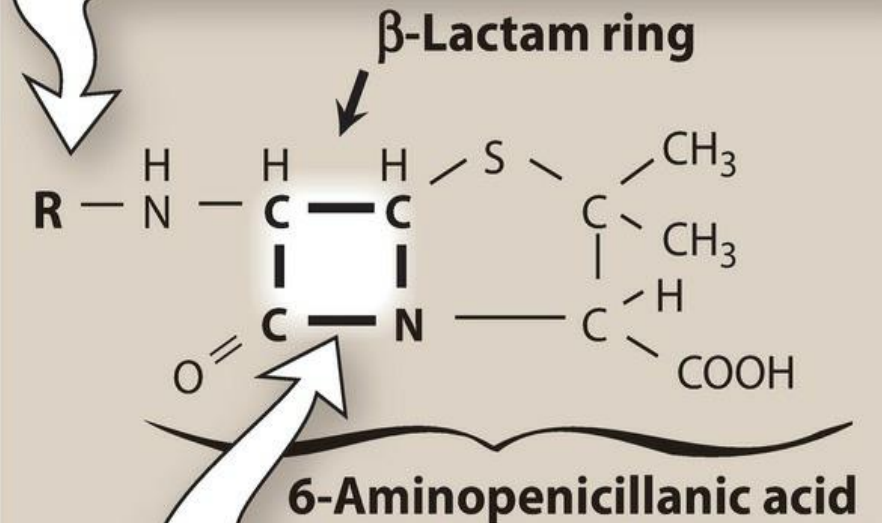

OTHER ANTIBIOTICS	
<i>Colistin</i>	COLY-MYCIN M
<i>Daptomycin</i>	CUBICIN
<i>Fosfomycin</i>	MONUROL
<i>Polymyxin B</i>	GENERIC ONLY
<i>Vancomycin</i>	VANCOCIN

PENICILLINS

- **Classification**
- All penicillins are derivatives of **6-aminopenicillanic acid** and contain a **beta-lactam ring structure** that is essential for antibacterial activity.
- Penicillin subclasses have **additional chemical substituents (R group)** that confer differences in antimicrobial activity, susceptibility to acid and enzymatic hydrolysis, and biodisposition.

Nature of the R group determines the drug's stability to enzymatic or acidic hydrolysis and affects its antibacterial spectrum.

Site of hydrolysis by bacterial penicillinase or by acid.

PENICILLINS

Pharmacokinetics

A. Routes of administration:

- The route of administration of a β -lactam antibiotic is determined **by the stability of the drug to gastric acid** and *by the severity of the infection*.

PENICILLINS

Pharmacokinetics

A. Routes of administration:

- The combination of *ampicillin with sulbactam*, ticarcillin with clavulanic acid, and piperacillin with tazobactam, and antistaphylococcal penicillins **nafcillin** and **oxacillin** must be administered **intravenously (IV)** or **intramuscularly (IM)**.

❑ *Penicillin V, amoxicillin, and dicloxacillin* are available only as oral preparations.

❑ Others are effective by the oral, IV, or IM routes.

Stable to acid, permitting oral administration

Natural penicillins

→ *Penicillin V*

Antistaphylococcal

→ **Dicloxacillin**

Methicillin

Nafcillin

Oxacillin

Extended spectrum

→ **Ampicillin**

→ **Amoxicillin**

→ **Amoxicillin + clavulanic acid**

Ampicillin + sulbactam*

Antipseudomonal

Piperacillin

Piperacillin + tazobactam*

Stable to penicillinase

PENICILLINS

Pharmacokinetics

2- Depot forms:

- Procaine penicillin G and benzathine penicillin G are administered IM and serve as depot forms.
- They are slowly absorbed into the circulation and persist at low levels over a long time period.

PENICILLINS

Pharmacokinetics

B. Absorption:

- Most of the penicillins are **incompletely** absorbed after oral administration, and they **reach the intestine** in sufficient amounts to affect the composition of the intestinal flora.
- **Food decreases the absorption** of all the **penicillinase-resistant penicillins** because as **gastric emptying time increases**, the drugs are **destroyed by stomach acid**. Therefore, they should be taken **on an empty stomach**.

Absorption of most oral penicillins (amoxicillin being an exception) is impaired by food, and the drugs should be administered at least 1–2 hours before or after a meal.

PENICILLINS

Pharmacokinetics

C. Distribution:

- All the penicillins distribute **well & cross** the **placental barrier**, but none have been shown to have **teratogenic effects**.
- However, penetration into **bone** or **CSF** is **insufficient** for therapy **unless these sites are inflamed**.

PENICILLINS

Pharmacokinetics

D. Excretion:

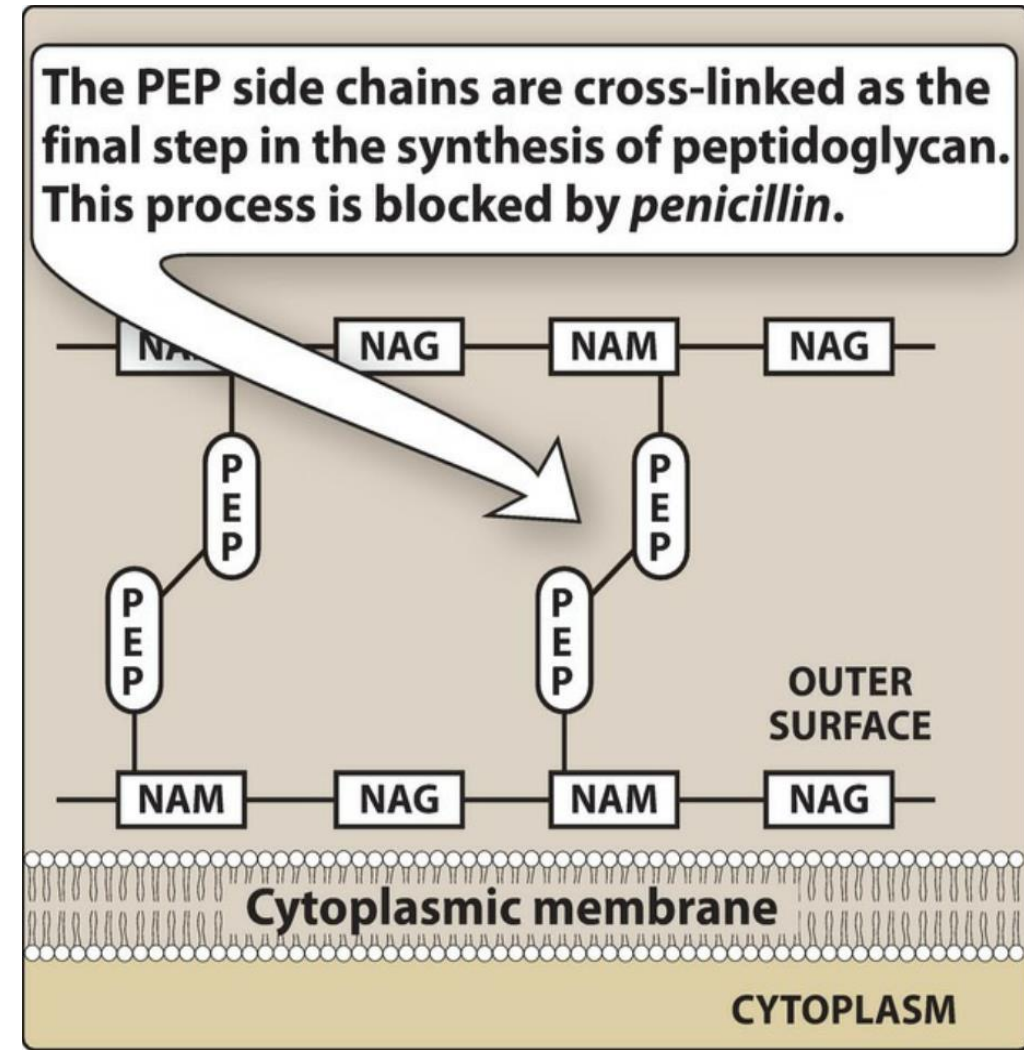

- The primary route of excretion is by glomerular filtration.
- Patients with **impaired renal function** must have dosage regimens adjusted.
- Nafcillin and oxacillin are metabolized in the liver.
- Probenecid **inhibits the secretion of penicillins** by competing for active tubular secretion via the organic acid transporter and, thus, can **increase** blood levels.

PENICILLINS

Mechanisms of Action and Resistance

❑ Beta-lactam antibiotics are **bactericidal drugs**. They *act to inhibit cell wall synthesis* by the following steps:

1. **Binding** of the drug to specific **enzymes** (**penicillin-binding proteins** [pbps]) located in the bacterial cytoplasmic membrane;
2. **Inhibition** of the **transpeptidation** reaction that cross-links the linear peptidoglycan chain constituents of the cell wall; and
3. Activation of **autolytic enzymes** that cause lesions in the bacterial cell wall and **cell death**.

Bacterial cell wall of gram-positive bacteria. NAM = N-acetylmuramic acid; NAG = N-acetylglucosamine; PEP = cross-linking peptide.

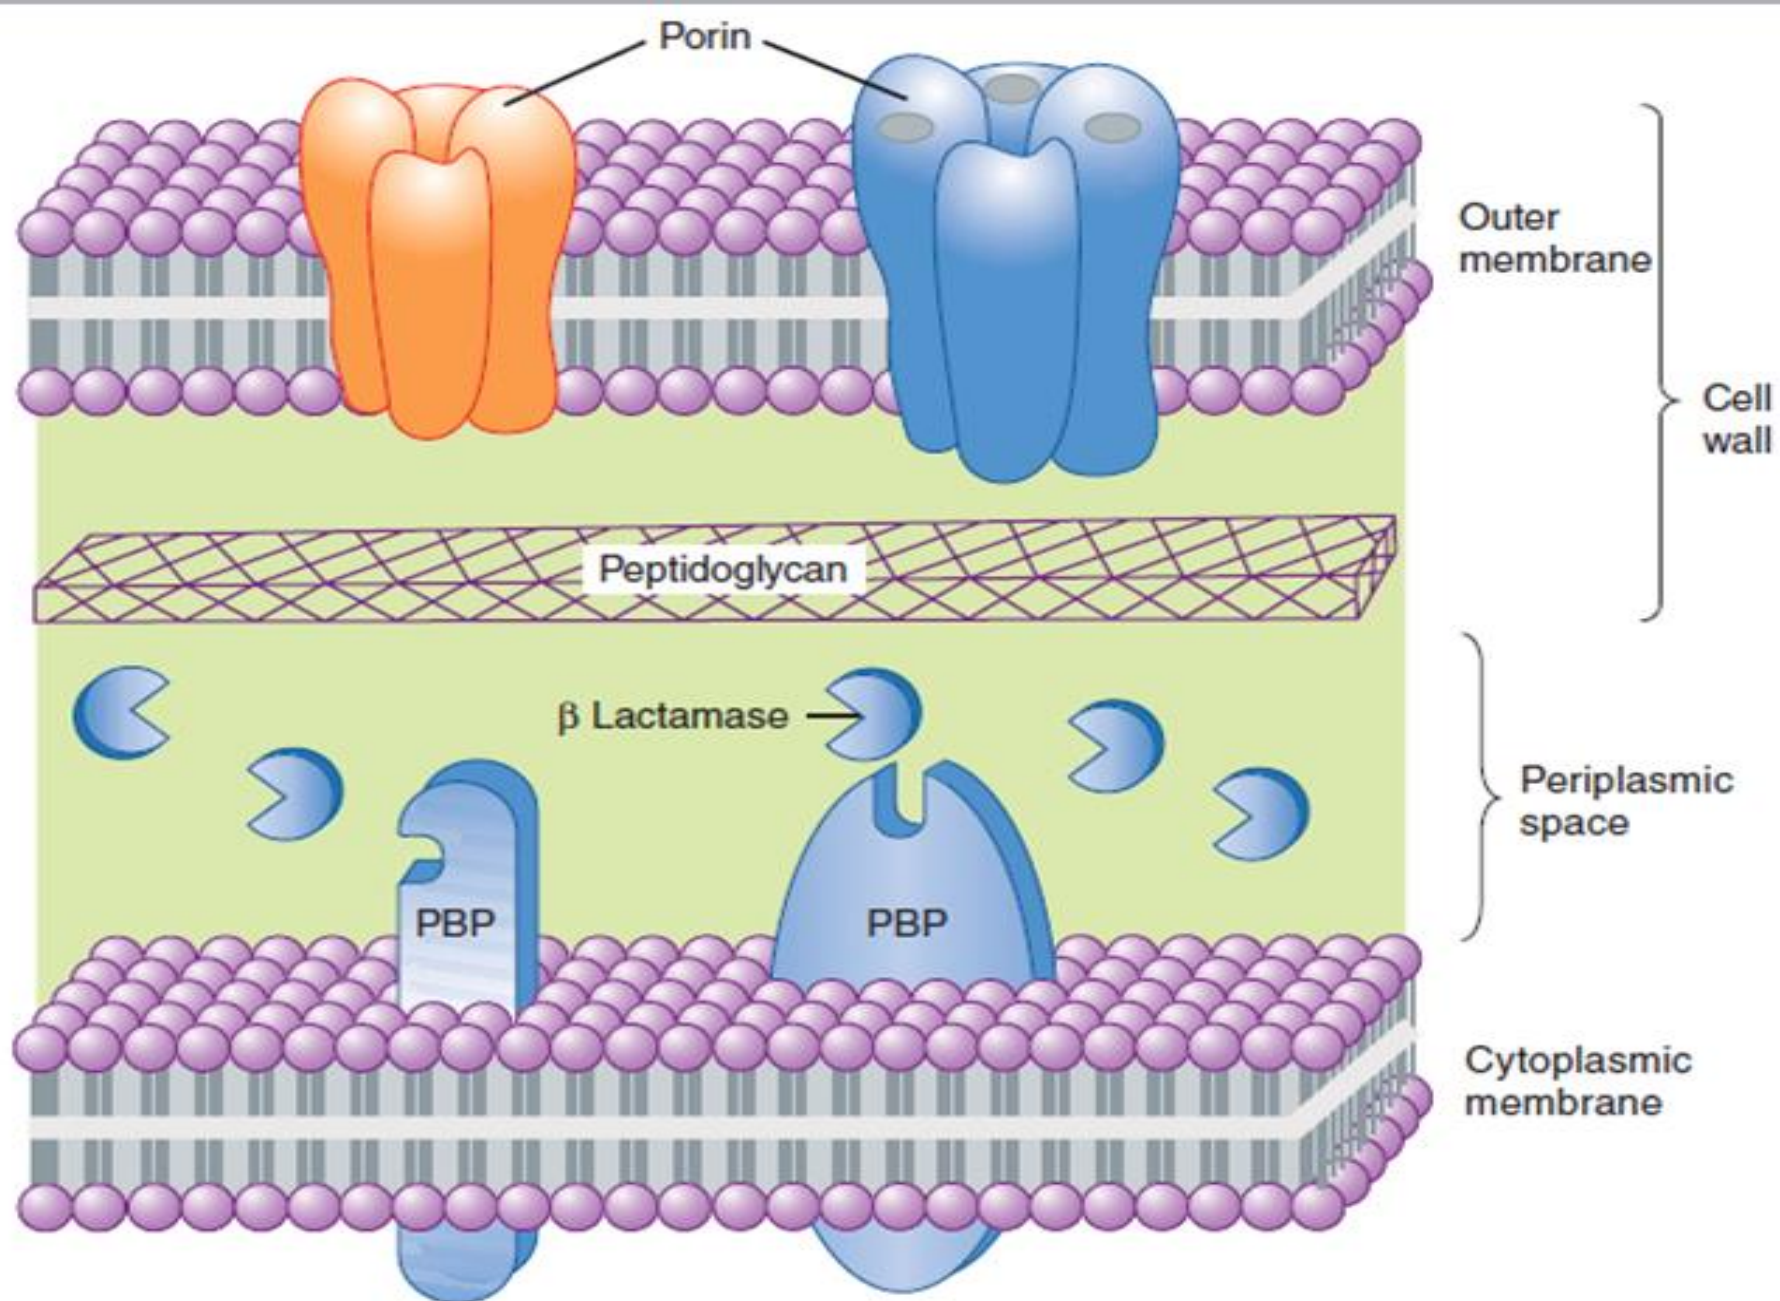

FIGURE 43–1 Beta-lactams and bacterial cell wall synthesis. The outer membrane shown in this simplified diagram is present only in gram-negative organisms. It is penetrated by proteins (porins) that are permeable to hydrophilic substances such as beta-lactam antibiotics.

PENICILLINS

- **Mechanism of bacterial resistance:**

- 1. β -Lactamase production**

- The formation of beta-lactamases (penicillinases) by most **Staphylococci** and many **gram-negative organisms**.

- **Inhibitors** of these bacterial enzymes (eg, **clavulanic acid, sulbactam, tazobactam**) are often used in combination with penicillins to prevent their inactivation.

Gram-Negative Bacteria Producing β -Lactamase:

1. Enterobacterales:

1. *Escherichia coli*
2. *Klebsiella pneumoniae*
3. *Enterobacter spp.*
4. *Serratia marcescens*
5. *Proteus spp.*
6. *Morganella morganii*
7. *Providencia spp.*
8. *Citrobacter spp.*

2. Non-Fermenters:

1. *Pseudomonas aeruginosa*
2. *Acinetobacter baumannii*
3. *Stenotrophomonas maltophilia*

3. Other Gram-Negative Bacteria:

1. *Haemophilus influenzae*
2. *Neisseria gonorrhoeae*
3. *Moraxella catarrhalis*

PENICILLINS

- **Mechanism of bacterial resistance:**

2. Structural change in target PBPs

- **PBPs** is responsible for methicillin resistance in **staphylococci** (MRSA) and for resistance to **penicillin G** in **pneumococci** (eg, PRSP, penicillin resistant *Streptococcus pneumoniae*) and **enterococci**.

3. Decreased permeability to the drug

- In some **gram-negative rods** (eg, *Pseudomonas aeruginosa*), changes in the **porin** structures in the outer **cell wall membrane** may contribute to resistance by impeding access of penicillins to PBPs.

PENICILLINS

- **Clinical Uses**

1. **Narrow-spectrum (penicillinase-susceptible agents)**

- ☐ **Penicillin G** is the prototype of a subclass of penicillins.

- **Clinical uses include** therapy of infections caused by common

1. **Streptococci,**

2. **Meningococci,**

3. **Gram-positive bacilli,**

4. **Spirochetes.**

PENICILLINS

1. Narrow-spectrum (**penicillinase-susceptible agents**)

□ **Penicillin G is the prototype of a subclass of penicillins.**

• **Resistant strains**

1. Many strains of *pneumococci* (penicillin-resistant *S. pneumoniae* [PRSP] strains).

2. *Staphylococcus aureus* and

3. *Neisseria gonorrhoeae* are **resistant** via production of **β-lactamases**.

PENICILLINS

1. Narrow-spectrum (**penicillinase-susceptible agents**)

□ **Penicillin G** is the prototype of a subclass of penicillins.

- Penicillin G remains the **drug of choice** for

1. Gas gangrene (*Clostridium perfringens*) and
2. Syphilis (*Treponema pallidum*).
3. Activity against **enterococci** is enhanced by coadministration of **aminoglycosides**.

□ **Penicillin V** is an oral drug used mainly in **oropharyngeal infections**.

Typical therapeutic applications of penicillin G

PNEUMOCOCCAL INFECTIONS

- Streptococcus pneumoniae is a major cause of bacterial pneumonia in all age groups and of bacterial meningitis in infants (excluding neonates) and adults.
- Pneumococcal pneumonia occurs more often in individuals with other chronic conditions, such as diabetes, asthma, and chronic lung disease.
- Resistance to *penicillin G* has greatly increased worldwide due to mutations in one or more of the bacterial penicillin-binding proteins.

Gram (+) cocci

Streptococcus pneumoniae*
Streptococcus pyogenes
Viridans streptococci* group

Gram (+) bacilli

Bacillus anthracis
Corynebacterium diphtheriae

Gram (–) cocci

Neisseria gonorrhoeae
Neisseria meningitidis

Gram (–) rods

Anaerobic organisms

Clostridium perfringens

Spirochetes

Treponema pallidum (syphilis)
Treponema pertenue (yaws)

Mycoplasma
Chlamydia
Other

GONORRHEA

- *Silver nitrate* drops in the eyes prevent gonococcal ophthalmia in newborns.
- Penicillinase-producing strains are treated using *ceftriaxone*, with *azithromycin* as a backup.

SYPHILIS

- A contagious venereal disease that progressively affects many tissues.
- A single treatment with *penicillin* is curative for primary and secondary syphilis. No antibiotic resistance has been reported.

PENICILLINS

2. Very-narrow-spectrum

❑ Penicillinase-resistant drugs (antistaphylococcal)

- This subclass of penicillins includes

1. **Methicillin** (The prototype, but rarely used owing to its **nephrotoxic** potential),
2. **Nafcillin**, And
3. **Oxacillin**.

- Their primary use is in the treatment of known or suspected **staphylococcal infections**.
- **Methicillin-resistant (MR) staphylococci** (*S. aureus* [MRSA] and *S. epidermidis* [MRSE]) are resistant to all penicillins and are often resistant to multiple antimicrobial drugs.

PENICILLINS

3. Wider-spectrum

□ Penicillinase-susceptible drugs (Semisynthetic penicillins)

A. Ampicillin and amoxicillin has a wider spectrum of antibacterial activity than penicillin G. Their clinical uses include indications similar to **penicillin G** as well as infections resulting from

1. *streptococci*,
2. *meningococci*,
3. *gram-positive bacilli*,
4. *spirochetes*.

1. *Enterococci*,
2. *Listeria monocytogenes*,

3. *Escherichia coli*,

4. *Proteus mirabilis*,

5. *Haemophilus influenzae*, and

6. *Moraxella catarrhalis*, although resistant strains occur.

PENICILLINS

3. Wider-spectrum

□ Penicillinase-susceptible drugs (Semisynthetic penicillins)

- When used in combination with inhibitors of **penicillinases** (eg, clavulanic acid), their antibacterial activity is often enhanced.
- In **enterococcal** and **listerial** infections, **Ampicillin** is synergistic with **aminoglycosides**.

PENICILLINS

b. Piperacillin and ticarcillin (Antipseudomonal penicillin)

- These drugs have activity against several **gram-negative rods**, including *Pseudomonas*, *Enterobacter*, and in some cases *Klebsiella species*.
- Most drugs in this subgroup have synergistic actions with **aminoglycosides** against such organisms.

PENICILLINS

b. Piperacillin and ticarcillin (Antipseudomonal penicillin)

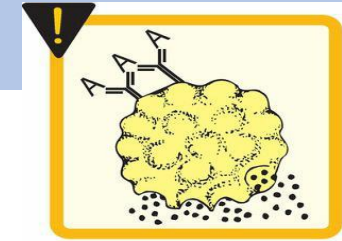

- *Piperacillin and ticarcillin* are susceptible to penicillinases and are often used in combination with penicillinase inhibitors (eg, tazobactam and clavulanic acid) to enhance their activity.

PENICILLINS

E. Adverse effects

1. Allergy

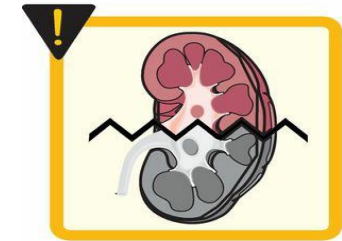

- Allergic reactions include urticaria, severe pruritus, fever, joint swelling, **hemolytic anemia**, nephritis, and anaphylaxis.
- **Methicillin** causes **interstitial nephritis**, and **nafcillin** is associated with **neutropenia**.
- Complete **cross-allergenicity** between different penicillins should be assumed.

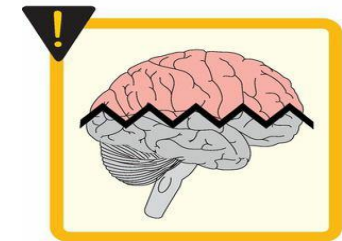

Hypersensitivity

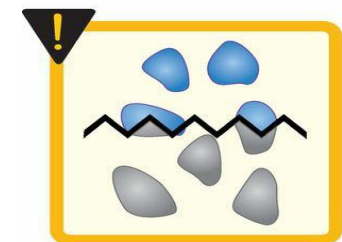

Diarrhea

Nephritis

Neurotoxicity

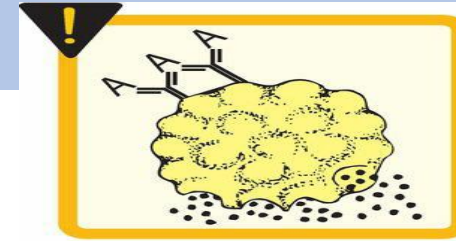

Hematologic toxicities

PENICILLINS

E. Adverse effects

2. **Gastrointestinal disturbances**

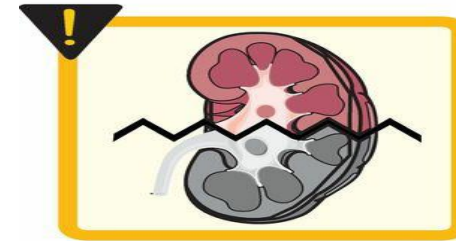

- Nausea and diarrhea may occur with oral penicillins, especially with ampicillin.
- Gastrointestinal upsets may be caused by direct irritation or by overgrowth of gram-positive organisms or yeasts.

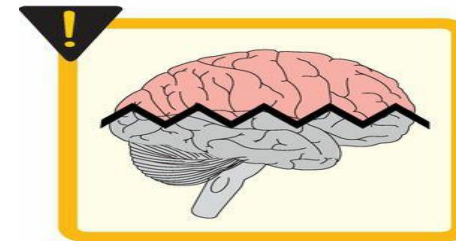

Hypersensitivity

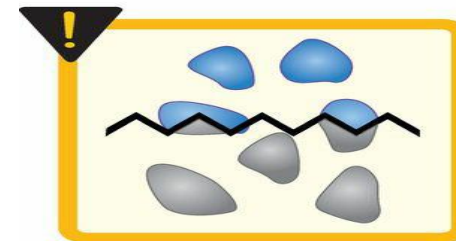

Diarrhea

Nephritis

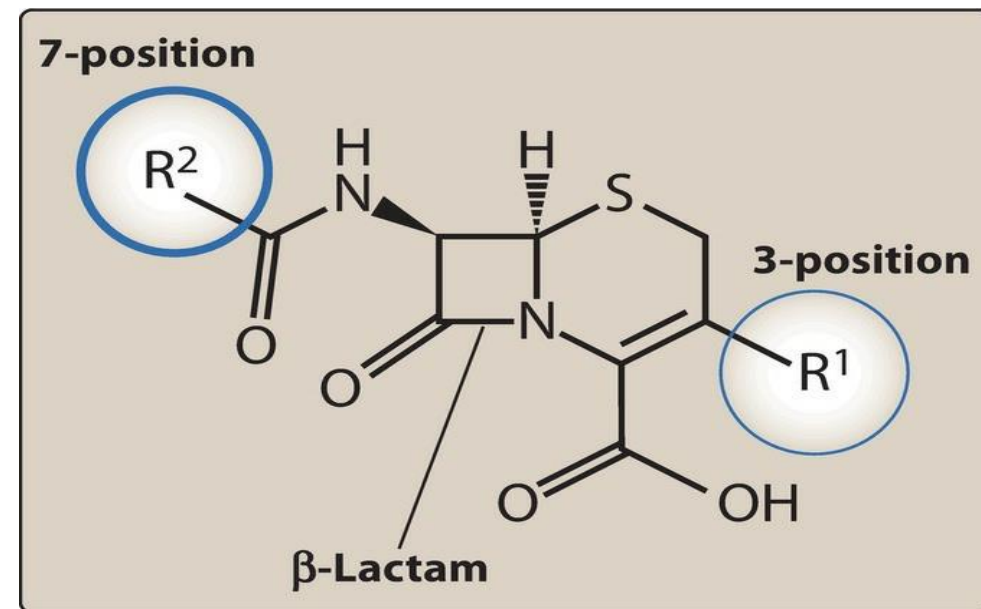

Neurotoxicity

Hematologic
toxicities

III. Cephalosporins

- The cephalosporins are β -lactam antibiotics that are closely related both structurally and functionally to the **penicillins**.
- Most cephalosporins are produced **semisynthetically** by the chemical attachment of side chains to **7-aminocephalosporanic acid**.
- Cephalosporins have the same mode of action as penicillins, and they are affected by the same resistance mechanisms.
- However, **they tend to be more resistant than the penicillins to certain β -lactamases**.

III. Cephalosporins

- **Pharmacokinetics:**

- Several cephalosporins are **available for oral use**, but most are administered **parenterally**.
- Cephalosporins with **side chains** may undergo **hepatic metabolism**, but the major **elimination** mechanism for drugs in this class is **renal excretion** via active tubular secretion.
- **Cefoperazone and ceftriaxone** are excreted **mainly in the bile**.
- *Most first- and second-generation cephalosporins do not enter the cerebrospinal fluid even when the meninges are inflamed.*

III. Cephalosporins

- Mechanisms of Action and Resistance
- Cephalosporins bind to PBPs on bacterial cell membranes to **inhibit** bacterial cell wall synthesis by mechanisms similar to those of the penicillins.
- *Cephalosporins* are **bactericidal** against susceptible organisms.

III. Cephalosporins

- **Mechanisms of Action and Resistance**

- Cephalosporins **less susceptible** to **penicillinases** produced by **staphylococci**, but many bacteria are resistant through the production of **other betalactamases** that can **inactivate** cephalosporins.
- Resistance can also result from decreases in membrane permeability to cephalosporins and from changes in PBPs.
- **Methicillin-resistant staphylococci** are also **resistant** to **cephalosporins**.

III. Cephalosporins

- Clinical Uses

1. **First-generation drugs**

- **Cefazolin** (parenteral) and **cephalexin** (oral) are examples of this subgroup.

➤ They are active against *gram-positive cocci*, including *staphylococci* and common *streptococci*.

➤ Many strains of *E coli* and *K pneumoniae* (**Gram-negative rods**) are also sensitive.

- Clinical uses include **treatment of infections** caused by these organisms and **surgical prophylaxis in selected conditions**.

First-generation cephalosporins

Cefazolin

Cephalexin

Cephadrine

Cefadroxil

III. Cephalosporins

2. Second-generation

- It have slightly **less activity against gram-positive organisms** than the first-generation drugs
- But **have an extended gram-negative coverage** such as **H. influenzae**, **Klebsiella species**, **Proteus species**, **Escherichia coli**, and **Moraxella catarrhalis**,
- Marked differences in activity occur among the drugs in this subgroup.

Second-generation cephalosporins

Proteus mirabilis

Anaerobic organisms**

Cefotetan,
Cefoxitin,
Cefamandole,
Cefuroxime,
Cefaclor

III. Cephalosporins

2. Second-generation

▪ Examples of clinical uses include infections caused by the:

1. *Gram -ve Anaerobe Bacteroides fragilis* (cefotetan, cefoxitin). They are the only cephalosporins with considerable activity against **gram-negative anaerobic bacteria**

2. Sinus, ear, and respiratory infections caused by *H influenzae* or *M. catarrhalis* (cefamandole, cefuroxime, cefaclor).

Second-generation cephalosporins

Gram (+) cocci

Staphylococcus aureus*
Streptococcus pneumoniae

Haemophilus influenzae
Klebsiella pneumoniae
Proteus mirabilis

Anaerobic organisms**

III. Cephalosporins

3. Third-generation drugs:

- (eg, **ceftazidime**, cefoperazone, **cefotaxime**, **ceftriaxone** cefixime)
- 1. It include **increased activity against gram-negative organisms**, resistant to other β -lactam drugs and ability to penetrate the blood-brain barrier (**EXCEPT** cefoperazone and cefixime).
- 2. Most are active against *Providencia*, *Serratia marcescens*, and
- β -lactamase producing strains of *H influenzae* and *Neisseria*.

Third-generation cephalosporins

Gram (+) cocci

Streptococcus pneumoniae
Streptococcus pyogenes
Anaerobic streptococci

Haemophilus influenzae
Klebsiella pneumoniae
Proteus mirabilis
Pseudomonas aeruginosa[†]
Serratia marcescens

III. Cephalosporins

3. Third-generation drugs:

- **Ceftriaxone and cefotaxime** are currently the most active cephalosporins against *penicillin-resistant pneumococci* (PRSP strains).
- Also have activity against *Pseudomonas* (**cefoperazone**, **ceftazidime**) and *B fragilis* (**ceftizoxime**).
- **Ceftriaxone** (parenteral) and **cefixime** (oral), currently drugs of choice in *gonorrhea*.

III. Cephalosporins

4. Fourth-generation drugs

- **Cefepime** combines the **gram-positive** activity of first-generation agents with the wider **gram-negative spectrum** of third-generation cephalosporins.
- **Cefepime** is more *resistant to beta-lactamases* produced by **gram-negative organisms**, including *Enterobacter*, *Haemophilus*, *Neisseria*, and some *penicillin resistant pneumococci*.
- **Ceftaroline** has activity in infections caused by **methicillin-resistant staphylococci**.

Fourth-generation cephalosporins

Antibacterial coverage comparable to that of the third-generation class; however, demonstrate greater stability against β -lactamases

III. Cephalosporins

Adverse effects

1. Allergy—Cephalosporins cause a range of allergic reactions from skin rashes to anaphylactic shock.

❑ These reactions occur **less frequently** with cephalosporins than with penicillins.

❑ **Complete cross-hypersensitivity** between different cephalosporins should be assumed.

❑ **Cross-reactivity between penicillins and cephalosporins** is incomplete (5–10%).

III. Cephalosporins

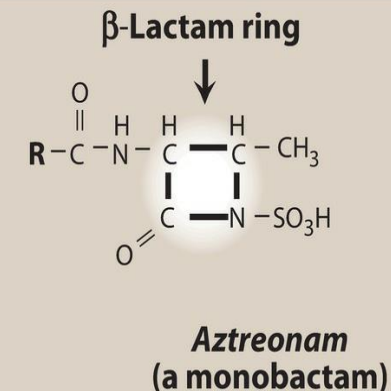

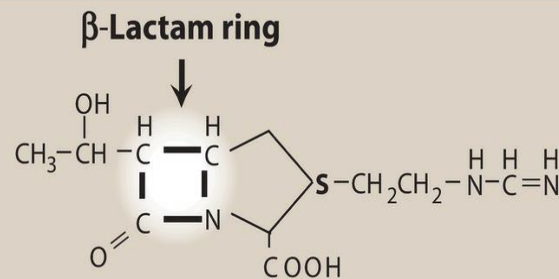

Adverse effects

2. Cephalosporins may cause **pain** at **intramuscular** injection sites and **phlebitis** after **I.V** administration.
3. They may increase *the nephrotoxicity* of *aminoglycosides* when the two are administered together.

IV. OTHER BETA-LACTAM DRUGS:

A. Aztreonam

- Aztreonam is a **monobactam** that is **resistant** to β -lactamases produced by certain **gram-negative rods**, including *Klebsiella*, *Pseudomonas*, and *Serratia*.
- The drug has **no activity** against **gram positive bacteria** or **anaerobes**.

IV. OTHER BETA-LACTAM DRUGS:

A. Aztreonam

- Aztreonam is administered **intravenously** and is eliminated via **renal tubular secretion**.
- Its half-life is **prolonged** in renal failure.
- **Adverse effects** include **gastrointestinal upset** with possible **superinfection**, **vertigo** and **headache**, and rarely **hepatotoxicity**, **skin rash**
- **NO cross allergenicity** with penicillins.

IV. OTHER BETA-LACTAM DRUGS:

B. Imipenem, Doripenem, Meropenem, and Ertapenem: parenterally

❑ These drugs are **carbapenems** (chemically different from penicillins but retaining the **beta-lactam ring structure**)

Anaerobic organisms

Clostridium species
Peptococcus species
Peptostreptococcus species
Propionibacterium species
Bacteroides species
Fusobacterium species

Spirochetes
Mycoplasma
Chlamydia

Other

Proteus species
Providencia species
Pseudomonas aeruginosa
Salmonella species
Serratia species

IV. OTHER BETA-LACTAM DRUGS:

B. Imipenem, Doripenem, Meropenem, and Ertapenem: parenterally

❑ They have wide activity against

1. **Gram-positive cocci** (including some penicillin resistant pneumococci),
2. **Gram-negative rods,**
3. **Anaerobes.**

❑ For **pseudomonal infections**, they are often used in combination with an **aminoglycoside**.

❑ MRSA strains of staphylococci are **resistant**.

IV. OTHER BETA-LACTAM DRUGS:

B. Imipenem, Doripenem, Meropenem, and Ertapenem: parenterally

- **Imipenem** is rapidly **inactivated** by renal **dehydropeptidase-I** and therefore it is administered in fixed combination with **cilastatin**, an inhibitor of this enzyme.
- **Cilastatin**
 - 1) **increases** the plasma half life of imipenem and
 - 2) **inhibits** the formation of potentially **nephrotoxic metabolite**.

IV. OTHER BETA-LACTAM DRUGS:

B. Imipenem, Doripenem, Meropenem, and Ertapenem: parenterally

- Adverse effects of imipenem-cilastatin include
 1. Gastrointestinal distress,
 2. Skin rash, and,
 3. At very high plasma levels, CNS toxicity (confusion, encephalopathy, seizures).
- ❑ There is **partial cross allergenicity** with the penicillins.

IV. OTHER BETA-LACTAM DRUGS:

C. Beta-Lactamase Inhibitors

- **Clavulanic acid, sulbactam, and tazobactam** are used in fixed combinations with certain **hydrolyzable penicillins**.
- They are most **active** against **plasmid-encoded beta-lactamases** such as those produced by

1. Streptococci,

2. Gonococci,

3. E coli,

4. H influenzae.

IV. OTHER BETA-LACTAM DRUGS:

C. Beta-Lactamase Inhibitors

- Clavulanic acid, sulbactam, and tazobactam
- They are **NOT good inhibitors** of inducible chromosomal beta-lactamases formed by

1. *Enterobacter*,

2. *Pseudomonas*, and

3. *Serratia*.

IV. Other Cell Wall Or Membrane-active Agents:

A. Vancomycin

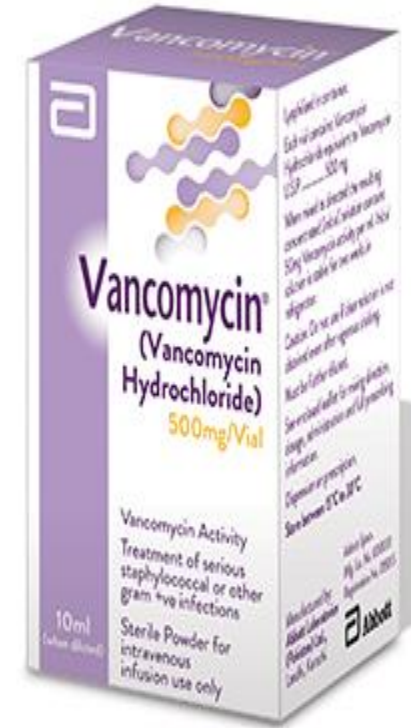

- Vancomycin is a **bactericidal** glycoprotein that **binds** to the *d-Ala-d-Ala* terminal of the ascent peptidoglycan pentapeptide side chain and **inhibits transglycosylation**.
- This action **prevents elongation** of the peptidoglycan chain and interferes with crosslinking.

IV. Other Cell Wall Or Membrane-active Agents:

A. Vancomycin

- **Resistance** in strains of **enterococci** (vancomycin-resistant enterococci [VRE]) and **staphylococci** (vancomycin-resistant *S aureus* [VRSA]) involves a **decreased affinity of vancomycin for the binding site**.

IV. OTHER CELL WALL OR MEMBRANE-ACTIVE AGENTS:

A. Vancomycin

- Vancomycin has a narrow spectrum of activity and is *used for*
 1. Serious infections caused by **drug-resistant gram-positive organisms**, including methicillin resistant staphylococci (MRSA)
 2. In combination with **ceftriaxone** for treatment of **penicillin-resistant streptococcus pneumoniae** (PRSP).
 3. Vancomycin is a backup drug for treatment of infections caused by **clostridium difficile**.

IV. OTHER CELL WALL OR MEMBRANE-ACTIVE AGENTS:

A. Vancomycin

- Toxic effects of vancomycin include #
 1. Chills, fever,
 2. Phlebitis,
 3. Ototoxicity, and
 4. Nephrotoxicity
 5. Rapid intravenous infusion may cause diffuse flushing (“red man syndrome”) from histamine release.

Anaerobic organisms

Clostridium species**

Spirochetes

Mycoplasma

Chlamydia

Other

Actinomyces

IV. Other Cell Wall Or Membrane-active Agents:

B. Fosfomycin

- ❑ Fosfomycin is an **antimetabolite inhibitor** of **cytosolic enolpyruvate transferase**.
- ❑ This action **prevents** the formation of **N-acetylmuramic acid**, an essential precursor molecule for **peptidoglycan chain formation**.

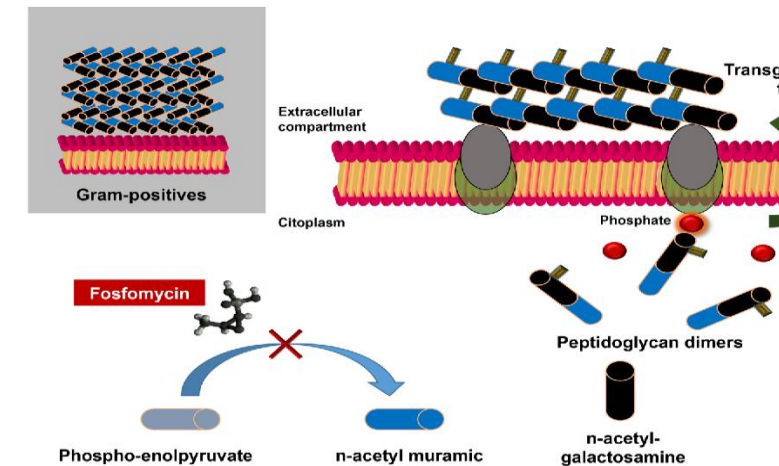

Figure 1 Mechanism of action of fosfomycin. Impact on synthesis of bae

IV. OTHER CELL WALL OR MEMBRANE-ACTIVE AGENTS:

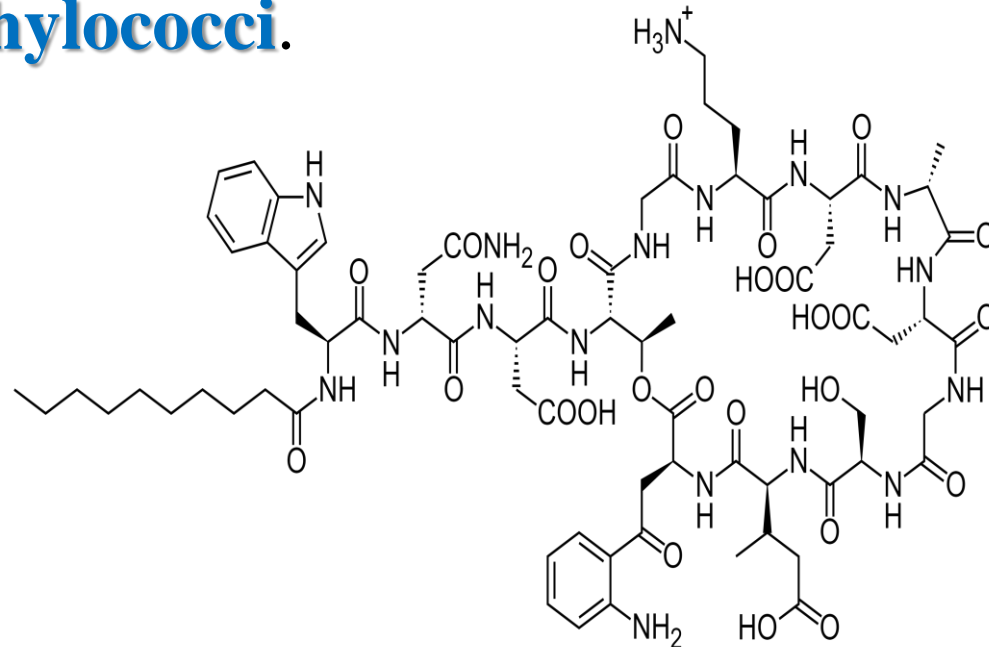

B. Fosfomycin

- ❑ Fosfomycin is *excreted by the kidney*, with urinary levels *exceeding the minimal inhibitory concentrations (MICs)* ,So It is **indicated for urinary tract infections** caused by *E. coli* or *Enterococcus faecalis*.
- ❑ It maintains high concentrations in the urine over several days, allowing for a **one-time dose**
- ❑ **Adverse effects** include diarrhea, vaginitis, nausea, and headache.

IV. Other Cell Wall Or Membrane-active Agents:

C. Daptomycin

- Daptomycin is a **bactericidal**, a novel cyclic lipopeptide with spectrum similar to vancomycin **but active against vancomycin-resistant strains of enterococci and staphylococci.**

Gram (+) cocci

Enterococcus faecalis

Enterococcus faecium

Gram (-) cocci

Gram (-) rods

Anaerobic organisms

Spirochetes

Mycoplasma

Chlamydia

Other

IV. Other Cell Wall Or Membrane-active Agents:

C. Daptomycin

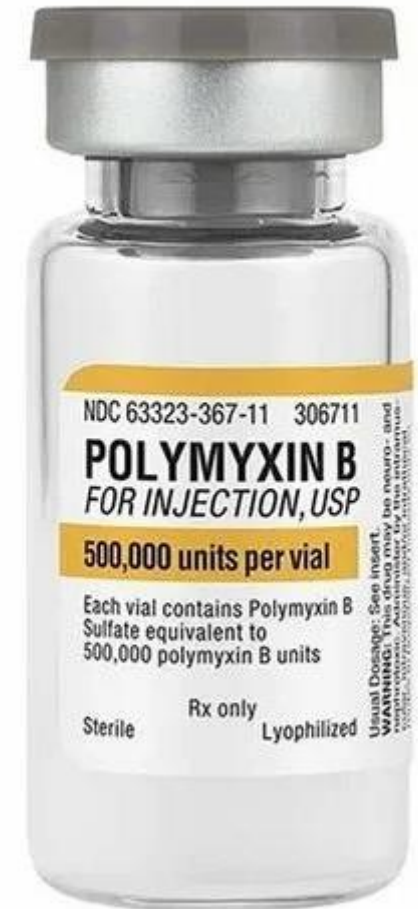

- Daptomycin is indicated for the treatment of complicated skin and skin structure infections and bacteremia caused by *S. aureus*.
- Daptomycin is **inactivated by pulmonary surfactants**; thus, it should never be used in the treatment of **pneumonia**.
- **Creatine phosphokinase** should be monitored since daptomycin may cause **myopathy**.

Iv. Other Cell Wall Or Membrane-active Agents:

D. Polymyxins

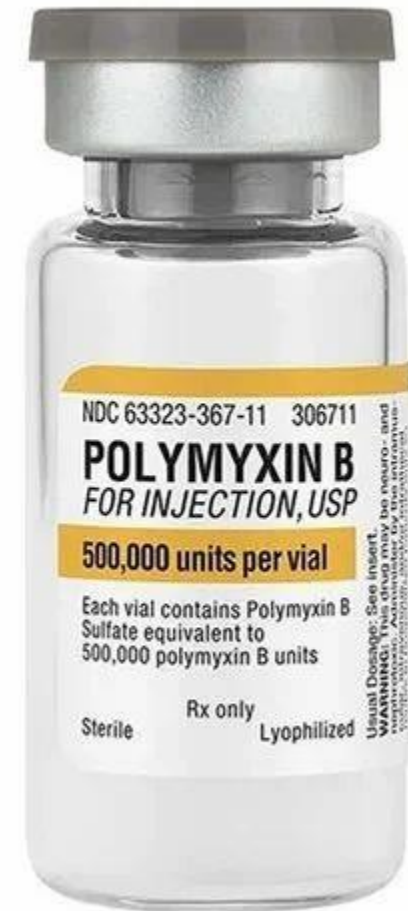

- Are **cation polypeptides** that bind to **phospholipids** on the bacterial cell membrane of **gram-negative bacteria**.
- They have a **detergent-like effect** that disrupts cell membrane integrity, leading to leakage of cellular components and ultimately cell death.

IV. Other Cell Wall Or Membrane-active Agents:

D. POLYMYXINS

- Polymyxins are **concentration-dependent bactericidal** agents with activity against
 1. ***P. aeruginosa***,
 2. ***E. coli***,
 3. ***K. pneumoniae***,
 4. ***Acinetobacter* species**, and
 5. ***Enterobacter* species**.

IV. Other Cell Wall Or Membrane-active Agents:

D. POLYMYXINS

- Only two forms of polymyxin are in clinical use today,
 1. **Polymyxin B**
 2. **Colistin** (polymyxin E).
- **Polymyxin B** is available in **parenteral, ophthalmic, otic,** and **topical** preparations.

IV. Other Cell Wall Or Membrane-active Agents:

D. POLYMYXINS

- **Colistin** is only available as a **prodrug, colistimethate sodium**, which is **administered IV or inhaled via a nebulizer**.
- The use of these drugs has been limited for a long time, due to the increased **risk of nephrotoxicity and neurotoxicity** (slurred speech, muscle weakness) when used systemically.
